Imagine a 30 cube object with votation axis that projected onto z-axis defined by vector u. Rotate it

Shankar R Asst Professor, CSE, BMSIT&M

(A)

and find the final rotation matrix R'. Show all 5 steps involved in it with I review of operation.

When an object is to be rotated about an axis that is parallel to one of co-ordinate axis, we need to accomplish the required rotation in five steps given that is it, projected on to 2-axis. (defined by vector w).

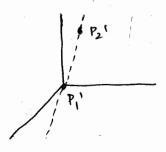

Let us assume that notation axis is defined by two points P, and B. The components of rotation-augs vector,

unit rotation-cixix vector uix, $u = \frac{V}{u} = (a,b,c)$.

$$a = \frac{x_2 - x_1}{|V|}$$
 $b = \frac{y_2 - y_1}{|V|}$ $c = \frac{z_2 - z_1}{|V|}$

Step 1: Translate the object to that notation axis panes through w-ordinate origin.

> considering counter-clockwise rotation viewing along me axis from P2 to P1, the translation matrix is given as

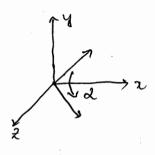

Step@:- Rotate the object to that axis of rotation with one of the w-ordinate axis.

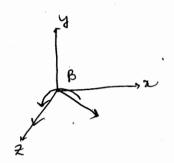

Shankar R Asst Professor, CSE, BMSIT&M

It can be done in 2 steps.

(a) -> rotare about x axis get the vector u'in x & plane

(15) -> rotate about y-axix ger it to winuide with 2-axis.

> notation angle x' can be determined by dot product of u'.

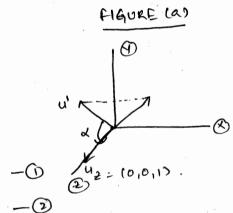

$$Cox \propto = \frac{u' \cdot u_2}{|u'| |u_2|} = \frac{c}{a}$$

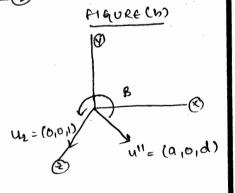

apply cross product

equate 10 4 0

duind = b

so,

Now, to rotate about y-axis, to wincide about as in figure us).

Shankar R Asst Professor, CSE, BMSIT&M

Consider, $\cos \beta = u'' \cdot u_z = a$

here, |421=14"1=1

equating 3 44

Step3):- Perform the specified rotation about the selected co-ordinate exis.

The votation angle (B) can now be applied as

$$R_{2}(\theta) = \begin{bmatrix} c_{01}\theta & -s_{11}\theta & 0 & 0 \\ s_{11}\theta & c_{01}\theta & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

Step A: Apply inverse rotations to bring the rotation and back to its original orientation. Apply Rill 4 Rylls).

Step 5: Apply inverse translations and the rotation matrix for 3D rotation can be written as

(53)

Demonstrare the 3D Translation and Reflection with Homogeneous Co-ordinates.

Shankar R Asst Professor, CSE, BMSIT&M

(A)

A possition P=(x,y,z) in three-dimensional space is translated to a location P'(x',y',z') by adding translation distrances tx,ty,tz to the cartesian w-ordinates of P.

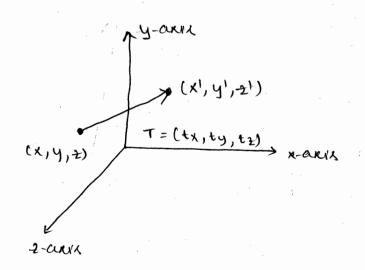

we can express in exy Matrix form as:

$$\begin{bmatrix}
 x' \\
 y' \\
 -1 \\
 1
 \end{bmatrix}
 =
 \begin{bmatrix}
 1 & 0 & 0 & tx \\
 0 & 1 & 0 & ty \\
 0 & 0 & 1 & ty \\
 0 & 0 & 0 & 1
 \end{bmatrix}
 \begin{bmatrix}
 x \\
 y \\
 -2 \\
 1
 \end{bmatrix}$$

(02)

An object is translated in 3 dimensions by transforming each of the defining wo-ordinate possitions for the object, then reconstructing the object at new location.

Consider, moving a co-ordinate position with translation vector

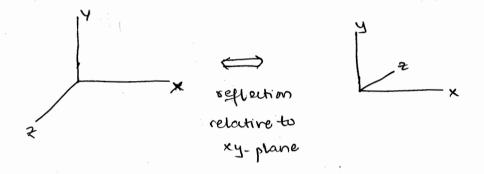

3-D REFLECTION:

Shankar R Asst Professor, CSE, BMSIT&M

It can be performed relative to a selected reflection and or with respect to a reflection plane. Reflections given the to a given axis equivalent to 180° rotations about that axis. When a reflection plane is a co-ordinate plane, we can think of transformation as a conversion between left handed frame and right handed frame.

An example of reflection that converts co-ordinate specification from right-handed system to left-handed system as shown below

The matrix representation for this reflection relative to the xy-

$$M_{\text{reflect}} = \begin{cases} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 1 \end{cases}$$

Transformation matrices for inverting x-coordinates or y co-ordinates are defined similarly, as reglections relative to the yz-plane or the xz-plane respectively.

- 54) Demonstrate the 3D Scaling and Shearing with Homogenous Coordinates.
- \Rightarrow Scaling:
 The most six expression for the 3-D scaling teronsformation of a position P=(x,y,z) erelative to the co-ordinate obligin is a simple extension of 2-D scaling. We just include the parameter of z-co-ordinate scaling in teranspormation matrix:

$$\begin{bmatrix} y' \\ y' \\ z' \\ 1 \end{bmatrix} = \begin{bmatrix} Sx & O & O & O \\ O & Sy & O & O \\ O & O & Sz & O \\ O & O & O & 1 \end{bmatrix} \cdot \begin{bmatrix} x \\ y \\ z \\ 1 \end{bmatrix} \longrightarrow 0$$

The three-dimensional scaling teransformation for a point position can be supresented as

where Scaling parameters SN, Sy, Sz are assigned any positive values. Explicit expressions for the scaling transformation relative to originate $N'=X\cdot SX$, $Y'=Y\cdot SY$, $Z'=Z\cdot SZ$

We can construct a scaling transformation with respect to only selected fixed position (x1, y1, z4) using the pollowing sequence:

- 1) Townslate the fixed point to the origin
- 2.) Apply the Scaling tolonsformation relative to the co-ordinate origin using equation (3.
- 3.) Teronolate the fixed point back to its original position.

The matrix depresentation for an arbitrary fixed-point scaling can be expressed as the concontenation of those thanslate-scale-tenanslate tenanslate tenanslate

$$T(x_{f},y_{f},z_{f}).S(Sx,Sy,Sz).T(-x_{f},-y_{f},-z_{f}) = \begin{cases} Sx & 0 & 0 & (1-Sx)x_{f} \\ 0 & Sy & 0 & (1-Sy)y_{f} \\ 0 & 0 & Sz & (1-Sz)z_{f} \\ 0 & 0 & 0 & 1 \end{cases}$$

Shearing:

These teconsformations can be used to modify object shapes, just as in two-dimensional opplications. They are also applied in 3-D viewing tecanisms for Perspective projections. Bor 3-D, we can also generate shears relative to the z-axis.

A general z-axis shearing transformation relative to a selected oreference position is produced with the following matrix:

Shearing portometers show and show can be assigned only steal values. The effect of this teransformation matrix is to alter the values for the x and y co-ordinates by an amount that is proportional to the distance from Zord, while leaving the z-co-ordinate unchanges.

55.) Explain the ambient light, diffuse deflection and specular diffuse deflection with equations.

=> Ambient light:-

In basic illumination model, we can interpolate background lighting by setting a general benightness level for a scene. This phoduces a uniform ambient lighting that is the same for all objects, and it appropriates the global diffuse eneflections from the various illuminated appropriated.

Assuming that we are clescopied only monotheromen lighting effects, Such as shades of grey, we designate the level for the ambient light in a some with an intervity parameter I.a. Each surjoin in the same is then illuminated with this background light. Reflections produced by ambient-light illuminations are simply a form of diffuse eneflection, and they are independent of the viewing direction and gratial orientation of a surjoin. However, the amount of the incident ambient light that is different deponds on surface optical properties, which delermine how much of the incident energy is viewleted and how much is assorbed.

ON Padiont-Energy
Direction

Radiont enougy from a Surface area element AA in direction of no relative to the surface normal direction is peroportional to los of no.

Diffuse Reflection:

the con model diffuse eneflections from a surface by assuming that the incident light is Scattered with equal intensity in all disentions, independent of the viewing Position. Such surfaces are called i'deal diffuse eneflected. They are also eneflected to as Lambertion reflected, because the ineflected enadight and 126

Prof Shankar R https://hemanthrajhemu.github.i

light energy from any point on the swiface is calculated with Lambert's cosine law, which states that the amount of stadions energy corning from any small swiface well add in a direction of m welster to the swiface normal is proportional to cost of.

Intensity: stadiant energy per unit time phojected acrea

da les dw = constant

The ambient contribution to the diffuse reflection at any point on a Swifare is Iombdiff: kd Ia.

The amount giruident light on a surface from a sound with circlensity Il is

Ilinuidant = Il 600

Diffuse eneflections ferom a light source with intensity II

Il, diff = Kd Il, incolor

= Kd Il coro.

At any surface position, we can denote the unit normal vector as N and the unit disection vector to a point society as L, as in fig. Then, Loso = N. L and the diffuse eleflection equation for single point-society illumination at a storface position can be expressed in the form.

Totaget N Source.

Il, diff = { kaIl(N.L), if N.L70

Using parameter to use con maite the 10 tal algorse-suffection equation for a single point source as.

Idy: { Ka Ia + IdIl (N.4), & N.L > 0 where L = Psource - Pswy 1

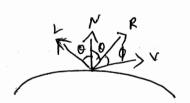

Ka Ja, if N.L & 0

1 Psource - Pswy 1

127

Specular leflection.

The beight spot, or specular eleflection, that we can see on a Shiry surface is the result of total, or near total, eightion of the incident light in a concentrated region around the Specular-eleflection angle. Figure shows the specular eleflection direction for a position on on illuminated surface. The specular reflection angle equals the angle of the incident light, with the two angles measured on apposite sides of the unit normal surface vector N. In the figure, R prepresents the unit vector in the direction of ideal specular eleflection, L is the unit vector directed toward the point light source, V is the unit vector pointing to the Viewer from the selected sweeper position. Anyle of 15 the viewer angle scalarie to the specular-reflection direction R.

The intensity of the specular eneflection and to a point light Source at a sharpace position with the calculation is:

Il, spec = { KsIl (V.R) ns, if V.R70 and N.L70 0.0 , if V.R50 and N.L 50

56) Emplain Open GIL 3D Viewing Functions

Shankar R Asst Professor, CSE, BMSIT&M

when we designate the viewing pageamoletic in Opential, an material is pormed of concatenated with the uporent model view moderia, consequently, this viewing material is combanied with any gometrial transformations we may have also specified. This composite material is then applied to transform object descripting in world coordinates to viewing coordinates.

glmaterixmode (GIL-MODELVIEW);

Vicuria paramoters are specified with the following On LO function, which is in the Open Go Lutility library because it involves the translation of redation or this basic Open bol lebiary.

glulookAt (xo, yo, Zo, Xorey, Yoref, Zoref, Vx, Vy, Vz),
values for all parameters in the function to be
assigned Louble-precision, floating-point values. This function
designates the origin of the viewing reference frame as
the world-roordinate position Po=(xo, yo, zo), the
reference position as Poref = (Xoref, Zoref), of the view up
vector as V=(Vx, Vy, Vz).

The positive 2 viewands for the viewing frame is in the direction N = Po-Pref, and the unit axis vectors for the viewing reference frame are calculated with Equations 1.

Because the viewing devention is along the - Zviewanis, this supereme possition from it, superied to as "lookalpoid," This usually taken to be some possition in the coto, of the supereme postition as the point at which we want to aim a common that is located at the viewing origin. The up orientation for the corners is designated with vector V, which is adjusted to a direction perpendicular to N.

The use do not implie glutookAt function, the default OpenGilviewing parameters are

$$P_0 = (0,0,0)$$

 $P_{\text{ref}} = (0,0,-1)$
 $V = (0,1,0)$

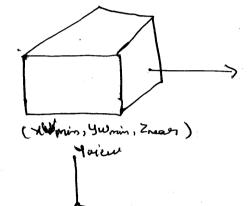

For these default values, the viewing reference prome us the same as the world from, with the viewing devention along the -ve zworld axis.

In many applications, we can conveniently use the default values for the viewer's parameters

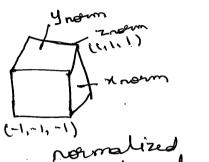

5H) Imagine you have a 3D object in front ofyour Shankar R Asst Professor, Illustrate how to Novimalize the transformation CSE, BMSITEM for an orthogonal projection?

using an orthregoral transfer of wordinate position onto the view plane , we obtain the projected position of any Spatial point (x,y,z) as simply (x,y). Thus, one we have established the limits per tere vieue volume, coordinate descriptions inside this occularizations parallelatopped are the peropertion wooderales, 4 they from he mapped into a refundized view volume without any further priopertion Processing. some graphics parkages use a unit cube joy this normalized view volume, with each of the x, y & 2 coordinates normalized in the sange from O to 1. Another normalization - transformation approach is to use a Symmetic cube, with coordinates in the range from 1401 Breause suren coordinates are often spenfied in a left handed reference peans, normalized woordends also are often Specified in a left handed System. This allows positive distances in the vicuour direction to be directly interpreted as distance from the screen. Thus, we can convert projection wordenates into politice will then be transferred to left - handed screen coordinate To illustrate the nouralisation transformation, use assure that the orthogonal-projection view volume is to be napped into the Symmetry

Nv; ene

Normalisation cube within left handed Reference frame.
Transforming the sistengular -parallelepiped view volume to a roundized cube is similar to converting the chipping winden into normalised Symmetri square. The normalisation transformation for the orthogonal view volume is

- Xumon + Xwomin Xworan - Xwonin ywman + ywn Zreag + Zjag Znear-Zjar Znear - Zpec

This materin is multiplied on the right by the composite Vieuries transformation to produce transformation from would coordinate to normalized orthogonalperopetion coordinates

(58) what is clipping and clipping window.

Shankar R Asst Professor, CSE, BMSIT&M

clipping:

Any procedure that identifies those portions of a picture that over either inside or outside of a specified region of a space is referred to as a clipping algorithm or simply clipping.

The region against which an object is clipped is called a clip window.

Types of clipping:

1. Point clipping

2. Line clipping

3. Polygon clipping

4 Curve Clipping

5. Text Clipping

Point Clipping :

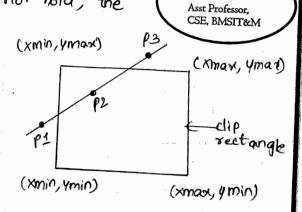

clipping Individual points:

The x coordinate boundaries of the clipping rectangle are xmin and Xmax, and the y coordinate boundaries are ymin and ymax, then the following inequalities must be statisfied for a point at (x, y) to be inside the clipping rectangle:

Xmin < x < xmax and ymin < y < ymax

If any of the four inequalities does not hold, the point is outside the clipping sectangle. (xmin, ymax)

- · PI point clipped away
- · P2 point is visible
 - P3 point clipped away.

Shankar R

Line clipping:

Cohen - suderland Algorithm >

Algorithm:

- 1. given a line segment with endpoint p1= (x1, y1) and p2= (x2, y2)
- 2. compute the 4-bit codes for each endpoint.
- # of both codes are 0000, line lies completely inside the window: pass the endpoints to the draw routine.
- # It both codes have a 1 in the same bit position, the line lies outside the window. It can be trivially rejected.
- 3. If a line cannot be trivially accepted on rejected, at least one of the two end points must lie outside the window and the line segment exosses a window edge. This line must be clipped at the window edge before being passed to the drawing routine.
- 4' Esamine one of the endpoints, say P1 = (x1, 11)

Read P1's 4-bit code in order: left to right, Bottom to TOP.

S. when a sit bit (1) is found, compute the intersection I of the corresponding window edge with the line from P1 to P2.

https://sh

Replace P1 with I and repeat the algorithm.

Shankar R Asst Professor, CSE, BMSIT&M

Basic algorithm:

- Accept lines that have both endpoints inside the region.
- -> Reject lines that have both endpoints le than 2min of ymin of greater than 2max of ymax
- steps on the clipped line segments.
- -) Assign a 4-bit code to each endpoint co, ct based on its position:
 - . 1st bit (1000) ! if y=ymax
 - , 2nd bit (0100): if y < ymin
 - . 3rd bit (0010): if 172max
 - · 4th bit (0001): if x c 2min
- → Test using bitwise functions

 if co|C1 = 0000

 accept (draw)

else if Co &C1 ≠0000

reject (don't draw)

else

clip and retest

<u>60</u> Bue Explain specular reflection.

Shankar R Asst Professor, CSE, BMSIT&M

soln!

Specular reflection, also known as regular reflection, is the universe-like reflection of weaves, such as light, from a surface. In this perocers, each incident ray is reflected at the same angle to the surface unormal as the incident ray, but on the opposing side of the surface horwal as the incident ray, The result is that an image reflected by the surface is rependenced in nirror-like fashion.

Reflection off of smooth surfaces such as mirrors or a calm body of water leads to a type of reflection business as specular reflection.

One application pertains to the relative difficulty of night driving on a wet asphalt hoodway lompared to a day asphalt.

sol. The 2-D Z-anis rotation equations one easily entended to three dimensions.

$$x' = n \cos \theta - y \sin \theta$$

 $y' = x \sin \theta + y \cos \theta$
 $x' = x$

Parameter & specifies the rotation angle about the zianis and z-coordinate values one unchanged by this transformation.

The homogenous -coordinate form is

$$\begin{bmatrix} n' \\ y' \\ z' \\ 1 \end{bmatrix} = \begin{bmatrix} \cos 0 & -8 \cos 0 & 0 \\ 8 \cos 0 & \cos 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} n \\ y \\ 3 \\ 1 \end{bmatrix}$$

which we can write as $P' = R_2(0) \cdot P$

Transfermation egns for relations about the other two coordinate aries can be obtained with a cyclic permutation of parameters my or and of parameters my or

Substituting permutations, we get eq ns for z-aris votation.

$$y' = y \cos \theta - y \sin \theta$$

$$\lambda' = y \sin \theta + y \cos \theta$$

$$\lambda' = x$$

Rotation of an object around n-anis can be obtained bimilarly.

A cyclic permutation of coordinates gives us the transformation equations for y-anis rotation.

$$x' = x \cos - x \sin 0$$

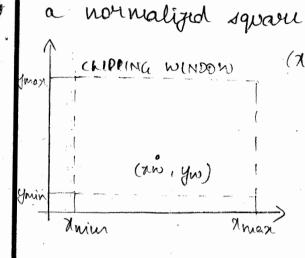

$$x' = x \sin 0 + x \cos 0$$

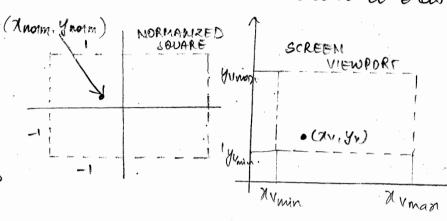

$$y' = y.$$

I wrangoing the respecting window into

Clip in > normalized co-predinates then the scene -) discription to a wiemport specified in screen co-ords.

Normalized coordinates are in the erarge from -1 to 1 clipping window algorithms are standardized such that objects outside the boundaries $x = \pm 1$ & $y = \pm 1$ are detected and removed from scene description.

Finally the wiewing transformation, has the objects in the viewport positioned within display window.

A point (xw, yw) in the dipping window is mapped to normalized coordinates position (xnorm, ynorm), then to a serum coardinate position (xv, yv) in a view port

with a neat diagram, illustrate
sutherband-Hodge man polygon dipping algorithm
an efficient method for dipping a convex
polygon field area, developed by sutherlandHodge man, is to send the polygon vertices
through each dipping stage so that a single
dipped vertex can be immediately passed to the
next stage. This diminates the need for an
output set of vertices at each dipping stage, and
it allows the boundary-dipping routines to
be implemented in parallel. The final output
is a list of vertices that describe the edges
of the dipped polygon fill area.

became the sutherland Hodgman algorithm phoduces only one list of output vertices, it cannot correctly generate the two output Polygons in figure that is the result of clipping the concave polygon shown in figure. However more processing steps can be added to the algorithm to allow it to produce multiple output vertex lists, so that general concave polygon clipping can be accompated.

https://hemanthrajhemu.github.io https://shankarrajagopal.github.io/

The general strategy in this algorithm is to send the pair, of end points (Shankar R ASSI PROFESSOR). The series of clippers cleft, right, bottom, top). There are four possible cases that need to be considered when proceeding a polygon eage against one of the dipping boundries. One possibility is that both the dipping points are inside the dipping boundary, other possibilities could have both end points outside the dipping window or one end points outside the dipping window.

As each successive point of end points is powed to one of the four clippers, an output is generated bot the next dipper according to the results of the following tests:

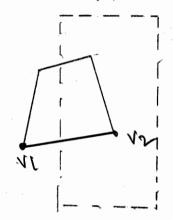

If the first input vertex is outside and the second vertex is inside the clipping window, both the the intersection point and the second vertex is one sent to the next Upper.

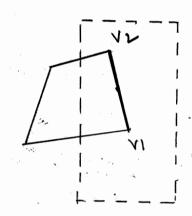

→ 4 both input vertices are inside this clipping - window border, only the second vertex is sent to the next clipper.

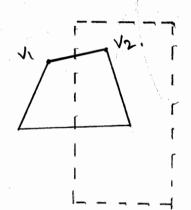

153

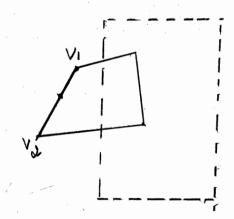

3) if the first vertex is imide the (Olipping window bolder and the second review is outside, only the polygon edge. intersection point with the Upping window is sent to the next dipper.

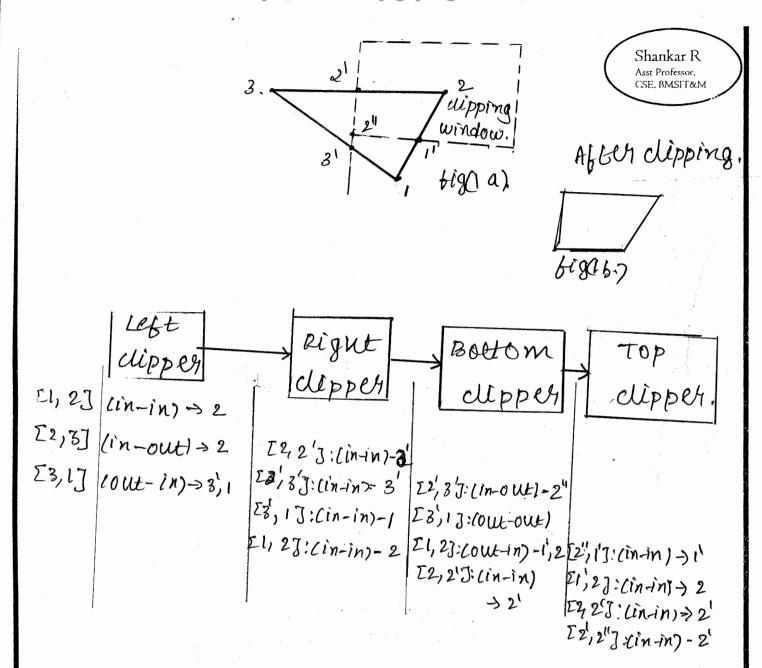

4) 16 both input vertices are outside this dipping window, no vertices are sent to the next dipper.

- 65) What is Quaternion? Explain the Quaternion methods for 3D Rotation?
- Shankar R Asst Professor, CSE, BMSIT&M
- A more efficient nuthod for generating a protation about an aubitanty selected ascis is to use a quaternion supercuentation to the votation transformation.
- omplex numbers, are useful in a number of computer-graphic powerbures. including the generation of fractal.
- one way to characterise a quaturion is an ordered pair, consisting of a scalar part and a vulor part:

9= (S, U)

through the coordinate origin is accomplished by first setting up a wait Quaternion with the scalar & weeter parts as follows.

Any point position p that is to be subtated by this Ouaternion (an be supourented in Quaternion subtation as

Shankar R Asst Professor, CSE, BMSIT&M

- Rotation of the point is then cavoried out with the Oualunion operation

when $q^{-1} = (s, -v)$ invoice q q

- This transformation produces the follow Quaternion

The 2nd term un this ordered pour us in rotated point position p! which us evaluated with wefor dot and (ross product as

part of q as V = (a, b, c)

https://shankarrajagopai.github.id

we obtain the elements for the composite rotation matrix

Shankar R Asst Professor, CSE, BMSIT&M

$$mg(0) = \begin{cases} 1-2b^2-2c^2 & 2ab-2sc & 2ac+2sb \\ 2ab+2sc & 1-2a^2-2c^2 & 2bc-2sa \\ 2ac-2sb & 2bc+2sa & 1-2a^2-2b^2 \end{cases}$$

-s Using the following tougonometric identities to simplify the teregnometric identities.

$$65^{2}\theta_{2} - 5in^{2}\theta_{2} = 1 - 25in^{2}\theta_{2} = 650$$

$$2 \cos \theta / 2 \sin \theta / 2 = \sin \theta$$

un can ouvouite as.

66. What is affine transformation?

A co-ordinate transformation of the form $x' = a_{xx}x + a_{xy}y + a_{xz}z + b_{x}$ $y' = a_{yx}x + a_{yy}y + a_{yz} + b_{y}$ $z' = a_{zx}x + a_{zy}y + a_{zz}z + b_{z}$

is whed an affine transformation tout of the transformed co-ordinates x', y' and z' is a linear function of the original co-ordinates x, y and z parameters are and by are constants determined by the transformation type.

The figure below shows an example of what we mean on the set, a cylinder has been built in a convenient place, and to a convenient size because of the real wirements of a scene, it is first scaled to be songer and thinner than it original design, rotated to a desired orientation in space, and then moved to a desired position the set of operations provioling for all such transformations, one known as the affine transformations of affines include translations and all linear transformations, like scale, rotate, and shear.

original cylinder model

transformed Cylindor. It has been scaled, octobed a translated. 159

-> Affine Transformations.

Let us first examine the affine transforms in 20 space where it is easy to illustrate them with diagrams, Then some we will have at the affiner in 30.

to enciden a point x= (x,y). Affine transformations of x are all transforms that can be written

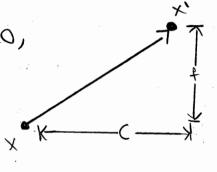

$$\chi' = \begin{bmatrix} 0x + by + c \\ dx + ey + t \end{bmatrix}$$

where a though fare scalars.

FOR example, if aic=7, and bid=0,

then we have a pure translation

$$\chi' = \begin{bmatrix} \chi + \zeta \\ 4 + \xi \end{bmatrix}$$

It pig =0 and cit =0 the me

have a pure suble.

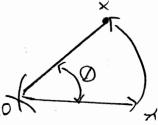

-sind, d=sind, ax

And, if a,e= (010, b= -sind,d=sind, ax

and c, +=0, Then we have a pure rotat

ion about the origin

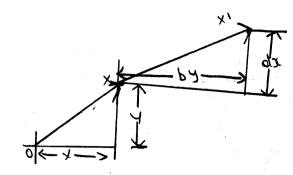

$$x_i = \begin{bmatrix} x \cos \theta - \lambda \cos \theta \end{bmatrix}$$

Finally it a, e=1, and c, f=0 me

emortenant stant such

$$x' = [x + by]$$

In sumary, we have the four basic affine transformations shown in the figure below.

- Otranslate moves a set of points of fixed distance in x and y',
- and y directions,
- @ Rotate votates a set of points about the origin,
- @ shear offsets a set of points a distance proportional to their I and y co-ordinates.

Note that only shear and stake change the shape determined by a set of points.

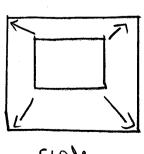

Translate

Rotate

suse

Matrix Representation of the Linear Transformortions.

The affine toan storms scale, rotate and shear one actually linear transforms and can be represented by a matrix multiplication of a point represented as a vector,

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} ax + by \\ dx + ey \end{bmatrix} = \begin{bmatrix} a & b \\ d & e \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix},$$

or x' zHx, where H is the matrix.

one very nice teature of the motils representation of the modern play hice to the out of the teat of the out of the out of the out of the simplest the out of the out

x'= R(H((x))

box, Hards-bors, slave-tel: 2 mortenost sort to somewar a conitable to the sort to somewar. Ist such check, we can remove the sort as a five a sort and the sort and the continuous to the continuous and sort and sort and sort and the sort that the sort are sort and so wor that the sort are sort and so work are sort and so wor that the sort are sort and so wor that the sort are sort and so wor that the sort are sort and so wor that are sort and so wor that the sort are sort and so wor that are sort and so wor that are sort as the sort are sort are sort and so wor that are sort and so wor that are sort and so wor that are sort as the sort are sort are sort as the sort are sort

x'=(RHS)x =Hx.

In motoix form, we can catled the linear transform as scale: $\begin{bmatrix} cx & 0 \end{bmatrix}$, Rotate: $\begin{bmatrix} cos\theta & -sin\theta \end{bmatrix}$, shear: $\begin{bmatrix} 1 & kx \\ ky & 1 \end{bmatrix}$, $\boxed{162}$

where sx and sy scale the x and y coordinates of a point, B is an angle of counterclockwise rotation around the arigin, Lx is a Lari's autal stead factor, and by is a vertical shear taxor.

-> Homogeneous co-ordinates

since the motilization is so handly for building up complex to the sold the transfer that the sold to the sold the sold the transform is to the the sold the

our first take our of our points $x=cx/\gamma$, expers them as >0 vectors [x] and make these into 30 vectors with identical 36d co-ordinates set to z:

$$\begin{bmatrix} x \\ -\frac{1}{2} \end{bmatrix} <= \begin{bmatrix} x \\ -\frac{1}{2} \end{bmatrix}$$

By convention, we can this coordinate the we co-ardinate, to distinguish it from the usual so 2 coordinate, we also extend our so matrices to 3b Lamogeneous form by appending an extra row and column, giving.

mote what happens when we multiply out so tomogeneous matrices by 3D tomogeneous vectors:

$$\begin{bmatrix} Q & b & 0 \\ d & e & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} X \\ Y \\ Z \end{bmatrix} = \begin{bmatrix} Qx + by \\ dx + ty \\ Z \end{bmatrix}$$

This is The same result as in 20, with

The exception of the extra w coordinate, whi

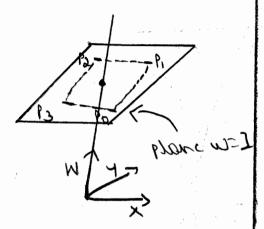

-h remain I. All we have reliably done is

to place all of our 20 points on the plane

w=I in so space, and now undo all the

operations on this plane, really, the operat

-ions are still so operations.

meters c and f in the matrix in the 3rd column:

$$\begin{bmatrix} 0 & b & c \\ d & c & f \\ 0 & 0 & J \end{bmatrix} \begin{bmatrix} x \\ y \\ J \end{bmatrix} = \begin{bmatrix} 0x + by + c \\ dx + cy + f \\ J \end{bmatrix}$$

en con now do translations as linear operations in hanage news coordinates! so, we can adob a final matrix to our catalog:

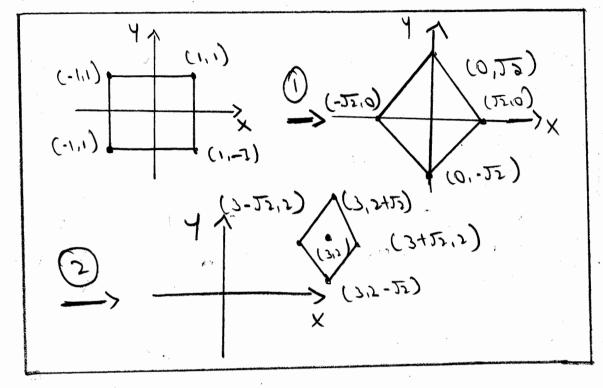

Translate: 0 7 AY

where Ix is the translation in the x direction and by is the translate in the y direction. The astate reader will see the trick behind the magic - 20 translation is now being expressed as a sheat in 30 space.

now, suppose we have a 2x2 countre central at the origin and we want to first totale the countre by USO

about its center and Then move the souther so its center is at (3,2), we can do This in tube steps, as shown in the diagram to the

·tupis

Mote that

verifying that we get The same besult shown in the . suppit

-> 30 Form of the Affine Transformations

now, we can extend all of these ideas to 30 in the following.

$$\begin{bmatrix} x \\ y \\ z \end{bmatrix} \Rightarrow \begin{bmatrix} x \\ y \\ z \\ z \end{bmatrix}.$$

The extra Cuth) coordinate is again called the w co-ordinate.

2. Use motivies to represent the 30 assire moustains in homo

general form. The following matrices constitute the basic

affire transforms in 30, expressed in homogeneous form.

In addition, there are those basic rotations in 30,

Pototion about x Qxiss. 0 cosox which 0 0 0 0 0 0 0 0 0

The rotations, specified in this was determine on

amount of rotation about each of the individual axes. or the coordinate system. The angles $\theta x_1 \theta y_1$ and θz result bellas elle exper ent trade nottotor to angles. They can be used to describe an off-axis rotation, tailgitum xintam sin inoitator share reles pains dona ved ion, Note, however, that The order of rotation assets the end result, so be sides specifying tales angles, an order of mostation must be specified. In general, after transform Int as suitatummas tan erro tud suitaborse ero monto order in which operation are done is highly important one can see this too rotations by computing the product Rox, Roy, Roz, and comparing with the result Obtained by The product ROZ, ROY, ROX.

68. What is color model? Explain the Reis

Any method for explaining the properties or behauser of color within some particular content es called a color model.

The RUB Color Model

According to the Ivistimulus thuosy of vision cour eyes precieve color through the stimulation of three visual pignents in the cones of the revine one of the pignents is most sensitive to light with a wantength of about 630 nm (red), and these has by Peace Sensitivity at about 530 nm (gener) and the third of about 530 nm (gener) and the third of about is most deceptive to light with a wantength is the basis for displaying color occupation a video monitor wing the twee primaries and gener and bleve there are deposed that there are primaries and generally given and bleve

delines on RiG and B arrey.

As worth xyz color system, the Reis color schem is an cadditive model Each color point within the unit cube can suppresent as a weighted vector sum at the primary colors, using unit vectors R, G and B

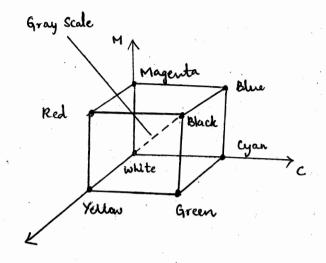

where parameters Rigard B are assigned values in the range from 0 to 1.0 for example.

volue (1,111)

Ciraystule color can be snepsnekned heltway between white and bleen (0.5,0.5,0.5)

69. Explain the CMY and CMYK rolor models. (

Shankar R. Asst Professor, CSE, BMSIT&M

A subtautive color model can be formed with the 3 primary colors cyan, magenta and yellow. When while light is virlated from Cyan colored ink the sufferted light contains only the green and thus component, and the ored component are absorbed. In the CMY model the spacial position (1,1,1) supresent black because all component of incident light are subtacted. The Deigin supresent while light. Equal amount of each of the perimary colors produces shades of grey along the ceuter main diagonal. I combination of eyan and magenta interpolaces the light similarly a combination of cyan and yellow produces green light and combination of magenta and yellow yields ared light.

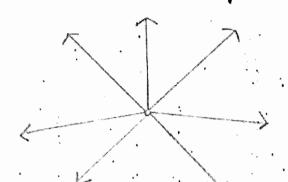

The CMY peinting procen often uses a collection of 4 ink dots, which are are arranged in a close pattern, In practise the CMY model in sufersed to as the CMYK model,

when k is the black color parameter of black Shankar R Ass Professor, CSE, BMSITEM Cyan, inagenta and yellow inks typically produces only shades of Grey. Same plotters produces a different color combination by spraying the ink for the 3 primary colors over each other and allowing them to unix before they dry, for black and while and grey scale paint printing, only the black such is

174

70 What is Light Source? Explain(the different types of light Source? Light Source: => An object that is emitting radient energy is called as light source that contribute to the lighting effects for other objects => We can model light sources with a Variety of shapes & characterstics => It is defined with number of properties by specify its position, colour, direction & shape => We assign light emitting properties using a single Value for each of the RenB Colon Components, which we can describe as the amount of the "intervity" of that color. The Different types of Light Sources are: 1) Point Light Source -> The Simplest model for an object that is emitting radient energy is a Point

light Source with a Single color, specified with 3 RepB Components.

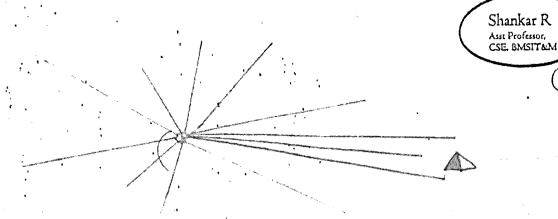

=) A. Point Source for a Scene by giving its Position & the cold of the emitted light. =) The Rays are generated along radially diverging Path from the Single Color Source Position.

=) This light-Source model is reasonable approximation for Sources whose dimension are small compared to the Size of object in that Scene.

2) Infinitely Distant Light Sources

=) A large light Source, Such as the Sun. that is very far from a Scene can also be approximiated as a point emitter, but there is little Variation in its directional effects =) The light path, from a distant light source to any position in the Scene is really constant.

=) we can simulate an infinitly distant light source by assigning it a cold value & a fixed director for the light hay from the Source =) The Vector for the emission direction & the light source color are needed in the illumination calculation; but not Position of Source 3) Radial Intensity Attenuation -=> As radiant energy from a light source travels outwards through space, its amplitude at any distance dr. from source is attenuated by the factor 1/d2 a surface close to the light source receives a higher incident light intensity from that sowe than more distant Surface.

=) However using an attenuation factor (Shankar R. Assr Professor, of 1/ds2 with a Point source does not a always Produce realistic Pictures =) The factor 1/di? tends to produce too much intensity Variation for objects that are close to the light Source => We can attenuate light intensities with an inverse greatestic function of Il that includes a linear term. Fradiatten (dl) = 1 aota, d, tazdi => The numerical values for the 6-efficient ao, a, E, az can then be adjusted to Produce optimal attenuation effects. =) We cannot apply intensity attenuation Calculation I to a point source at "infinity" because the distance of the light Source. , if source is infinty fi, haddatten = { 1.0, 1+ Source is in ao, +a,d, +a,d, 2, if Source is local

178

=) If we restrict the angular extent Shankar R Assr Professor, of any light cone so that 0° < 01 < 90° CSE BMSITAM then the object is within the spotlight. If con d \geq con Ol, as shown some or since or is core axis

=) It Volz. Vlight < cos Ol, however the object is outside the light cone.

Angular Intensity Attenuation:

=) For a directional light Source We can attenuate the light intensity angularly about the source as well as radially out from the Point-Source Position.

=> This allows intensity decreasing as we move faither from the cone axis.

=> A commonly used angular intensity attenuation function for a directional light source is fargette (d)=(d)

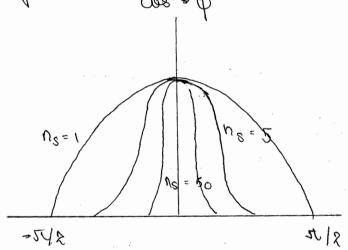

forgatten(ϕ)=(ϕ)=(ϕ), 0° $\leq \phi \leq 0$

180

=) Where the attenuation exponent (Shankar R. Assi Professior, CSE PRASTERIN at is assigned some positive value & angle I is measured from the cone axis. =) The greater the value for the attenuation esconent al, the smaller the value of the angular intensity function for a given Value of angle \$>0°. =) There is no angular attenuation if the light source is not directional =) we can express the general equation for angular attenuation as:if Source is not a 1,0, Spot light if Voly. Vlight = Cos << COS 01 (Voly Vlight), otherwise

71> Emplain the PHONG Model.

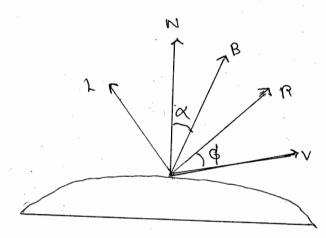

Thong suffection is an empirical model of local clumination. It describes the way a scentage reflects light as a combination of the difference suffection of rough surfaces with the specular suffection of sling swifaces. It is based on thoug's informal observation that sling surfaces have small without specular highlights, while dull swifaces have large highlights of more gradually.

Thong model sets
the intensity of
specular reflection to
cos no d

 $I_{l,specular} = W(\theta) I_{l} \cos^{n_s} \theta$ $0 \le W(\theta) \le l$ is called specular reflection coefficient If light direction Land viewing direction Varian (Asst Professor, CSE, BMSITEM)
